Character Strings

- A *string literal* is represented by putting double quotes around the text
- · Examples:

```
"This is a string literal."
"123 Main Street"
"X"
```

- Every character string is an object in Java, defined by the String class
- Every string literal represents a String object

The println Method

- In the Lincoln program from Chapter 1, we invoked the println method to print a character string
- The System.out object represents a destination (the monitor screen) to which we can send output

System.out.println ("Whatever you are, be a good one.");

object method name information provided to the method (parameters)

The print Method

- The System.out object provides another service
- The print method is similar to the println method, except that it does not advance to the next line
- Therefore anything printed after a print statement will appear on the same line
- See Countdown.java

String Concatenation

• The string concatenation operator (+) is used to append one string to the end of another

```
"Peanut butter " + "and jelly"
```

- · It can also be used to append a number to a string
- A string literal cannot be broken across two lines in a program
- See Facts.java

String Concatenation

- The + operator is also used for arithmetic addition
- The function that it performs depends on the type of the information on which it operates
- If both operands are strings, or if one is a string and one is a number, it performs string concatenation
- · If both operands are numeric, it adds them
- The + operator is evaluated left to right, but parentheses can be used to force the order
- See Addition.java

Quick Check

What output is produced by the following?

```
System.out.println("X: " + 25);
System.out.println("Y: " + (15 + 50));
System.out.println("Z: " + 300 + 50);
```

X: 25 Y: 65 Z: 30050

Escape Sequences

- · What if we wanted to print the quote character?
- The following line would confuse the compiler because it would interpret the second quote as the end of the string

```
System.out.println("I said "Hello" to you.");
```

- An escape sequence is a series of characters that represents a special character
- An escape sequence begins with a backslash character (\)

```
System.out.println("I said \"Hello\" to you.");
```

Escape Sequences

Esca

· Some Java escape sequences:

Meaning
backspace
tab
newline
carriage return
double quote
single quote
backslash

• See Roses.java

Quick Check

Write a single println statement that produces the following output:

"Thank you all for coming to my home tonight," he said mysteriously.

System.out.println("\"Thank you all for " +
 "coming to my home\ntonight,\" he said " +
 "mysteriously.");

Variables

- A variable is a name for a location in memory that holds a value
- A variable declaration specifies the variable's name and the type of information that it will hold

int total;
int count, temp, result;

Multiple variables can be created in one declaration

Variable Initialization

A variable can be given an initial value in the declaration

int sum = 0;
int base = 32, max = 149;

- When a variable is referenced in a program, its current value is used
- See PianoKeys.java

Assignment

- An assignment statement changes the value of a variable
- · The assignment operator is the = sign

total = 55;

- The value that was in total is overwritten
- You can only assign a value to a variable that is consistent with the variable's declared type
- See Geometry.java

Constants

- A constant is an identifier that is similar to a variable except that it holds the same value during its entire existence
- · As the name implies, it is constant, not variable
- The compiler will issue an error if you try to change the value of a constant
- In Java, we use the final modifier to declare a constant

final int MIN_HEIGHT = 69;

Constants

- · Constants are useful for three important reasons
- First, they give meaning to otherwise unclear literal values
 - Example: MAX_LOAD means more than the literal 250
- · Second, they facilitate program maintenance
 - If a constant is used in multiple places, its value need only be set in one place
- Third, they formally establish that a value should not change, avoiding inadvertent errors by other programmers

Primitive Data

- There are eight primitive data types in Java
- Four of them represent integers:
 - byte, short, int, long
- Two of them represent floating point numbers:
 - float, double
- One of them represents characters:
 - char
- · And one of them represents boolean values:
 - boolean

Numeric Primitive Data

• The difference between the numeric primitive types is their size and the values they can store:

<u>Type</u>	Storage	Min Value	Max Value
byte short int	8 bits 16 bits 32 bits	-128 -32,768 -2,147,483,648	127 32,767 2,147,483,647
long	64 bits	<-9 x 10 ¹⁸	> 9 x 10 ¹⁸
float double	32 bits 64 bits		n 7 significant digits h 15 significant digits

Characters

- · A char variable stores a single character
- · Character literals are delimited by single quotes:

```
'X'
         '$' ',' '\n'
```

· Example declarations:

```
char topGrade = 'A';
char terminator = ';', separator = ' ';
```

· Note the difference between a primitive character variable, which holds only one character, and a String object, which can hold multiple characters

Character Sets

- · A character set is an ordered list of characters, with each character corresponding to a unique number
- A char variable in Java can store any character from the Unicode character set
- The Unicode character set uses sixteen bits per character, allowing for 65,536 unique characters
- · It is an international character set, containing symbols and characters from many world languages

Copyright © 2017 Pearson Education, Inc

Characters

- The ASCII character set is older and smaller than Unicode, but is still quite popular
- · The ASCII characters are a subset of the Unicode character set, including:

uppercase letters lowercase letters punctuation digits

A, B, C, ... a, b, c, ...

period, semi-colon, ...

special symbols

0, 1, 2, ...

control characters

&, |, \, ... carriage return, tab, ...

R	<u></u>	വ	ما	a	r

- A boolean value represents a true or false condition
- The reserved words true and false are the only valid values for a boolean type

boolean done = false;

• A boolean variable can also be used to represent any two states, such as a light bulb being on or off

Expressions

- An expression is a combination of one or more operators and operands
- Arithmetic expressions compute numeric results and make use of the arithmetic operators:

Subtraction Multiplication Division Remainder

· If either or both operands are floating point values, then the result is a floating point value

Division and Remainder

 If both operands to the division operator (/) are integers, the result is an integer (the fractional part is discarded)

> 14 / 3 equals 4 8 / 12 equals 0

 The remainder operator (%) returns the remainder after dividing the first operand by the second

> 14 % 3 equals 2 8 % 12 equals 8

> > Copyright © 2017 Pearson Education, Inc

Quick Check

What are the results of the following expressions?

12 / 2 = 6 12.0 / 2.0 = 6.0 10 / 4 = 2 10 / 4.0 = 2.5 4 / 10 = 0 4.0 / 10 = 0.4 12 % 3 = 0 10 % 3 = 1 3 % 10 = 0

Operator Precedence

· Operators can be combined into larger expressions

```
result = total + count / max - offset;
```

- Operators have a well-defined precedence which determines the order in which they are evaluated
- Multiplication, division, and remainder are evaluated before addition, subtraction, and string concatenation
- Arithmetic operators with the same precedence are evaluated from left to right, but parentheses can be used to force the evaluation order

Quick Check	
In what order are the operators ev following expressions?	aluated in the
	* c - d / e 1 4 2
a / (b + c) - d % e 2 1 4 3	
a / (b * (c + (d - e)) 4 3 2 1))
	Copyright © 2017 Pearson Education, Inc.

Expression Trees The evaluation of a particular expression can be shown using an expression tree The operators lower in the tree have higher precedence for that expression a + (b - c) / d a - d

Assignment Revisited • The assignment operator has a lower precedence than the arithmetic operators First the expression on the right hand side of the = operator is evaluated answer = sum / 4 + MAX * lowest; 4 1 3 2 Then the result is stored in the variable on the left hand side

Assignment Revisited

• The right and left hand sides of an assignment statement can contain the same variable

First, one is added to the original value of count

Then the result is stored back into count (overwriting the original value)

Copyright © 2017 Pearson Education, Inc

Increment and Decrement

- The increment (++) and decrement (--) operators use only one operand
- · The statement

count++;

is functionally equivalent to

count = count + 1;

Copyright © 2017 Pearson Education, Inc

Increment and Decrement

 The increment and decrement operators can be applied in postfix form:

count++

· or prefix form:

++count

- When used as part of a larger expression, the two forms can have different effects
- Because of their subtleties, the increment and decrement operators should be used with care

Assignment Operators

- Often we perform an operation on a variable, and then store the result back into that variable
- Java provides assignment operators to simplify that process
- · For example, the statement

```
num += count;
```

is equivalent to

num = num + count;

Copyright © 2017 Pearson Education, Inc

Assignment Operators

 There are many assignment operators in Java, including the following:

<u>Operator</u>	<u>Example</u>	Equivalent To		
+=	x += y	x = x + y		
-=	ж -= у	x = x - y		
*=	x *= y	x = x * y		
/=	x /= y	x = x / y		
% =	x %= y	ж = ж % у		

Copyright © 2017 Pearson Education, Ir

Assignment Operators

- The right hand side of an assignment operator can be a complex expression
- The entire right-hand expression is evaluated first, then the result is combined with the original variable
- · Therefore

```
result /= (total-MIN) % num;
```

is equivalent to

result = result / ((total-MIN) % num);

				•		
_/\	ssig	nmc	nt (1nn	rata	rc
$\overline{}$	ออเน			ノレモ	ומוט	ю

- The behavior of some assignment operators depends on the types of the operands
- If the operands to the += operator are strings, the assignment operator performs string concatenation
- The behavior of an assignment operator (+=) is always consistent with the behavior of the corresponding operator (+)

Data Conversion

Interactive Programs

Copyright © 2017 Pearson Education, Inc

Data Conversion

- · Sometimes it is convenient to convert data from one type to another
- · For example, in a particular situation we may want to treat an integer as a floating point value
- These conversions do not change the type of a variable or the value that's stored in it – they only convert a value as part of a computation

Data Conversion

- Widening conversions are safest because they tend to go from a small data type to a larger one (such as a short to an int)
- Narrowing conversions can lose information because they tend to go from a large data type to a smaller one (such as an int to a short)
- In Java, data conversions can occur in three ways:
 - assignment conversion
 - promotion
 - casting

Copyright © 2017 Pearson Education, Inc

Data Conversion Widening Conversions To Byte short, int, long, float, or double short int, long, float, or double int long, float, or double long float or double long float or double float double The short system int, long, float, or double long float or double long float or double long float or double float loybe, short, char, or int long, or float loybe, short, char, int, long, or float loybe, sho

Assignment Conversion

- Assignment conversion occurs when a value of one type is assigned to a variable of another
- · Example:

```
int dollars = 20;
double money = dollars;
```

- Only widening conversions can happen via assignment
- Note that the value or type of dollars did not change

Promotion

- *Promotion* happens automatically when operators in expressions convert their operands
- Example:

```
int count = 12;
double sum = 490.27;
result = sum / count;
```

 The value of count is converted to a floating point value to perform the division calculation

Copyright © 2017 Pearson Education, Inc

Casting

- Casting is the most powerful, and dangerous, technique for conversion
- Both widening and narrowing conversions can be accomplished by explicitly casting a value
- To cast, the type is put in parentheses in front of the value being converted

```
int total = 50;
float result = (float) total / 6;
```

 Without the cast, the fractional part of the answer would be lost

Interactive Programs

- Programs generally need input on which to operate
- The Scanner class provides convenient methods for reading input values of various types
- A Scanner object can be set up to read input from various sources, including the user typing values on the keyboard
- Keyboard input is represented by the System.in object

Copyright © 2017 Pearson Education, Inc

Reading Input

 The following line creates a Scanner object that reads from the keyboard:

Scanner scan = new Scanner(System.in);

- The new operator creates the Scanner object
- Once created, the Scanner object can be used to invoke various input methods, such as:

answer = scan.nextLine();

Copyright © 2017 Pearson Education, Inc

Reading Input

- The Scanner class is part of the java.util class library, and must be imported into a program to be used
- The nextLine method reads all of the input until the end of the line is found
- See Echo. java
- The details of object creation and class libraries are discussed further in Chapter 3

Ir	าท	ιıt	Τo	ke	ns
11	יקו	uι	10	'NC	110

- Unless specified otherwise, white space is used to separate the elements (called tokens) of the input
- White space includes space characters, tabs, new line characters
- The next method of the Scanner class reads the next input token and returns it as a string
- Methods such as nextInt and nextDouble read data of particular types
- See GasMileage.java
